NovaPay Financial Performance Analysis Report

Prepared by: Srushti Mahant Pawar

Project: NovaPay FP&A Analytics & Management Reporting

Tools Used: Excel, SQL, Python, Power BI

Date: October 12, 2026

1. Executive Summary

This project focuses on building a monthly FP&A reporting system for NovaPay, a fictional fintech company. The main objective was to organize financial and customer data, analyze performance against budget, run scenario analysis, and build an interactive Power BI dashboard for decision-making.

The project covers the complete analytics workflow, starting from raw data preparation, Excel financial modeling, SQL-based analysis, Python scenario analysis, and Power BI dashboard development. The final dashboard allows users to filter performance by month and review important business metrics such as total revenue, gross margin, EBITDA, active customers, revenue vs. budget, customer-level revenue, expenses, and CAC trends.

Overall, the dashboard helps identify revenue growth patterns, cost pressure, margin behavior, customer concentration, and areas where NovaPay can improve profitability.

2. Project Objective

The objective of this project was to create a complete FP&A reporting system that can help NovaPay track financial performance and make better business decisions.

The main goals were:

- Build a clean financial model in Excel.
- Use SQL queries to analyze revenue, expenses, customer performance, and KPIs.
- Use Python for variance analysis and scenario analysis.
- Build an interactive Power BI dashboard.
- Create a final business report with insights and recommendations.

3. Data Used

The project uses multiple business datasets related to NovaPay's financial and operating performance. The main tables used in the analysis include.

Revenue data: Monthly revenue by customer, including subscription revenue, transaction fee revenue, setup fee revenue, premium analytics revenue, transaction volume, and total revenue.

Expense data: Expense category-level data such as payroll, marketing spend, cloud hosting, rent, software, and customer support.

Budget data: Monthly budgeted revenue and budgeted EBITDA used for comparing actual performance against planned performance.

KPI data: Business performance metrics such as gross margin, churn rate, CAC, active customers, lost customers, new customers, average revenue, and net revenue.

Customer data: Customer names and customer-related revenue contribution.

Scenario inputs: Base, upside and downside assumptions used for scenario analysis.

4. Work Completed

The project was completed in multiple stages.

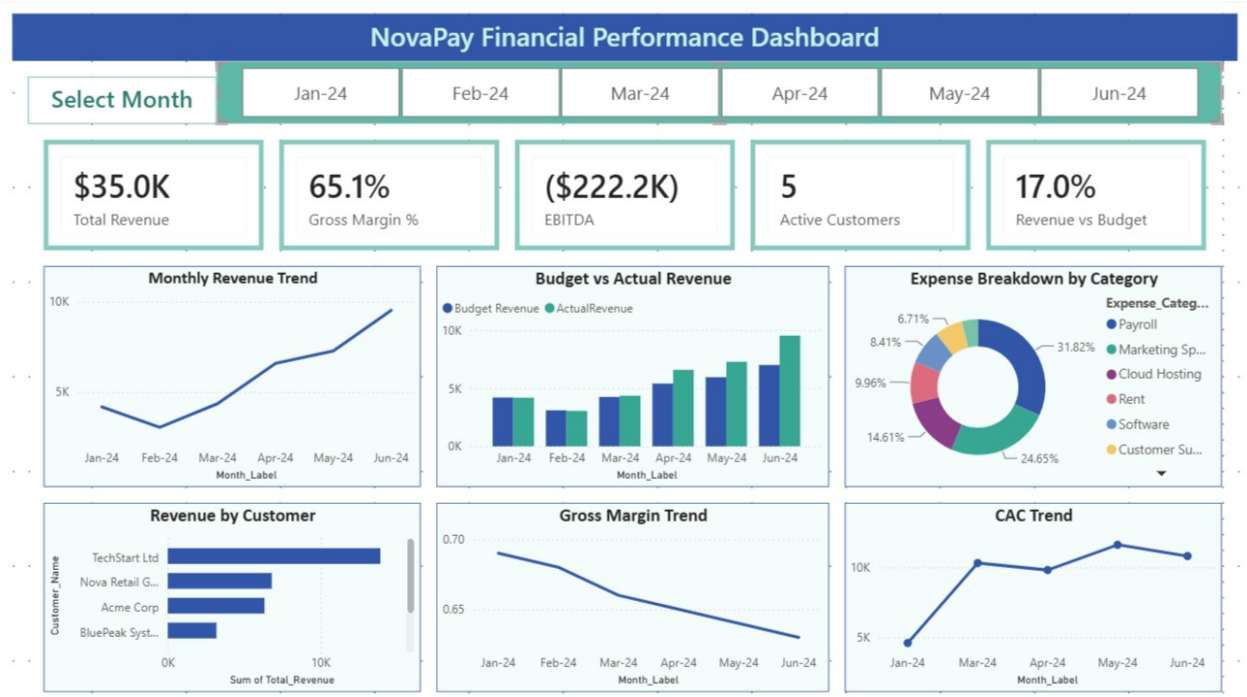

First, the Excel financial model was created and cleaned. The model includes separate sheets for revenue, expenses, budget, KPI metrics, customers, and scenario inputs.

Second, SQL queries were developed to analyze business performance. These queries helped summarize revenue, compare actuals against budget, review expenses, and identify key customer-level insights.

Third, Python (pandas) was used to rebuild the revenue-to-EBITDA bridge, budget vs. actual and expense overrun analysis, customer concentration, CAC, and a one-month base/upside/downside scenario analysis from June actuals. With only six months of data, this is scenario analysis rather than a statistical forecast.

Fourth, Power BI was used to build the final interactive dashboard. The dashboard includes KPI cards, revenue trends, budget comparison, expense breakdown, customer revenue analysis, gross margin trend, CAC trend, and a month slicer for interactivity.

5.Power BI Dashboard Overview

The Power BI dashboard provides a complete executive-level view of NovaPay's financial performance. It includes key performance indicators at the top and detailed visual analysis below.

The top KPI cards show total revenue, gross margin percentage, EBITDA, active customers, and revenue vs. budget. These metrics give a quick summary of business health.

The trend charts show how revenue, gross margin, and CAC changed across the months. The dashboard also includes budget versus actual revenue comparison, customer-wise revenue contribution, and expense category breakdown.

The month slicer allows the user to filter the dashboard by specific months such as Jan-24, Feb-24, Mar-24, Apr-24, May-24, and Jun-24.

6.Key Insights

- Monthly revenue grew from $4.2K in January to $9.5K in June (+128%), but EBITDA moved from −$35.0K to −$37.7K because operating expenses rose $5.9K while gross profit rose only $3.1K.
- Revenue beat budget by 17% over six months ($35.0K vs. $29.9K), but opex ran over plan in all six months, so EBITDA missed budget every month.
- Cloud hosting (+$5.1K) and marketing (+$4.9K) were the largest overruns. Payroll was the largest cost category at 31.8% of opex.
- TechStart Ltd generated 39.8% of six-month revenue; the top two customers generated 59%.
- From March to June, each new customer cost $9.8K–$11.6K in marketing, against under $2K a month in revenue per customer.
- Under all three scenarios, July EBITDA stays negative (−$38.3K to −$40.1K).

7.Business Recommendations

Based on the analysis, NovaPay should focus on improving profitability while continuing revenue growth.

First, the company should review major expense categories such as payroll, marketing, and cloud hosting to identify areas where costs can be optimized.

Second, NovaPay should monitor customer concentration risk. If only a few customers contribute most of the revenue, losing one major customer could affect overall performance.

Third, the company should improve EBITDA by controlling operating expenses and increasing higher-margin revenue streams.

Fourth, CAC should be monitored closely. If customer acquisition cost increases faster than revenue, the company may need to improve marketing efficiency.

Fifth, NovaPay should continue using the Power BI dashboard for monthly performance review, budget tracking, and management reporting.

8. Tools Used

The following tools were used in this project:

Excel: Used for financial modeling, organizing revenue and expense data, and preparing structured business tables.

SQL: Used for querying, summarizing, and analyzing financial and customer data.

Python: Used for variance analysis, customer concentration, CAC, and one-month scenario analysis.

Power BI: Used to create the final interactive dashboard with KPIs, charts, slicers, and executive-level visuals.

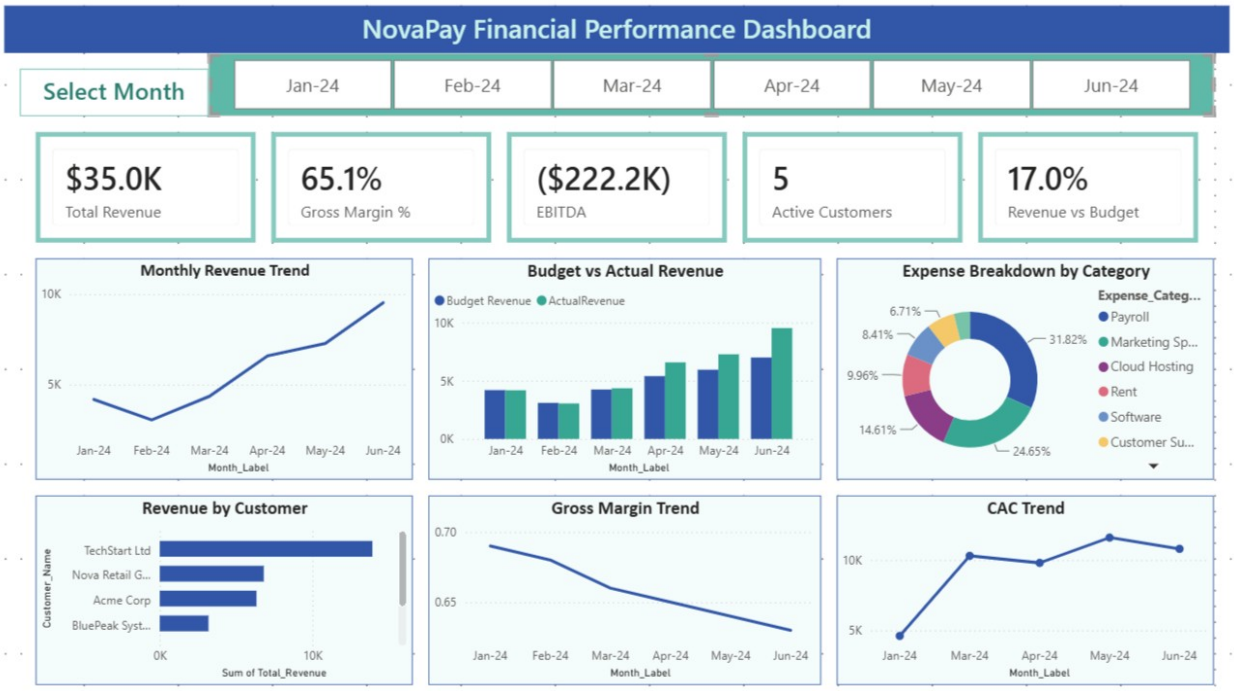

GitHub: Used to organize and share the complete project files.

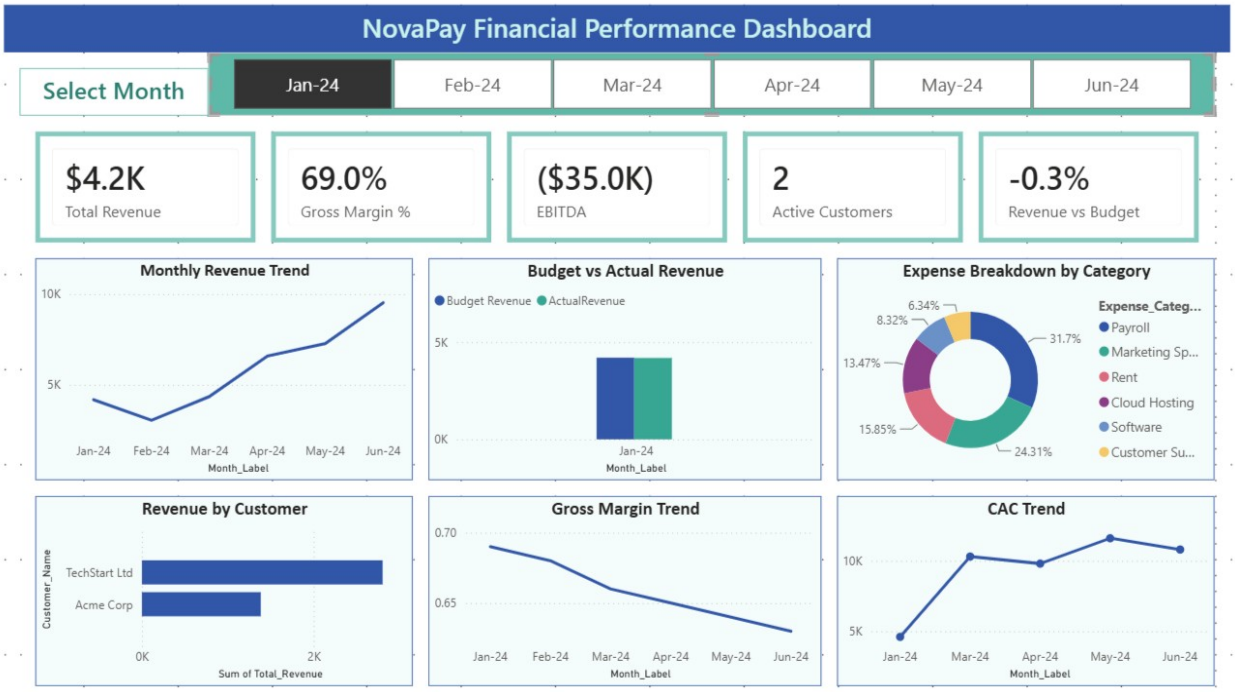

9. Final Conclusion

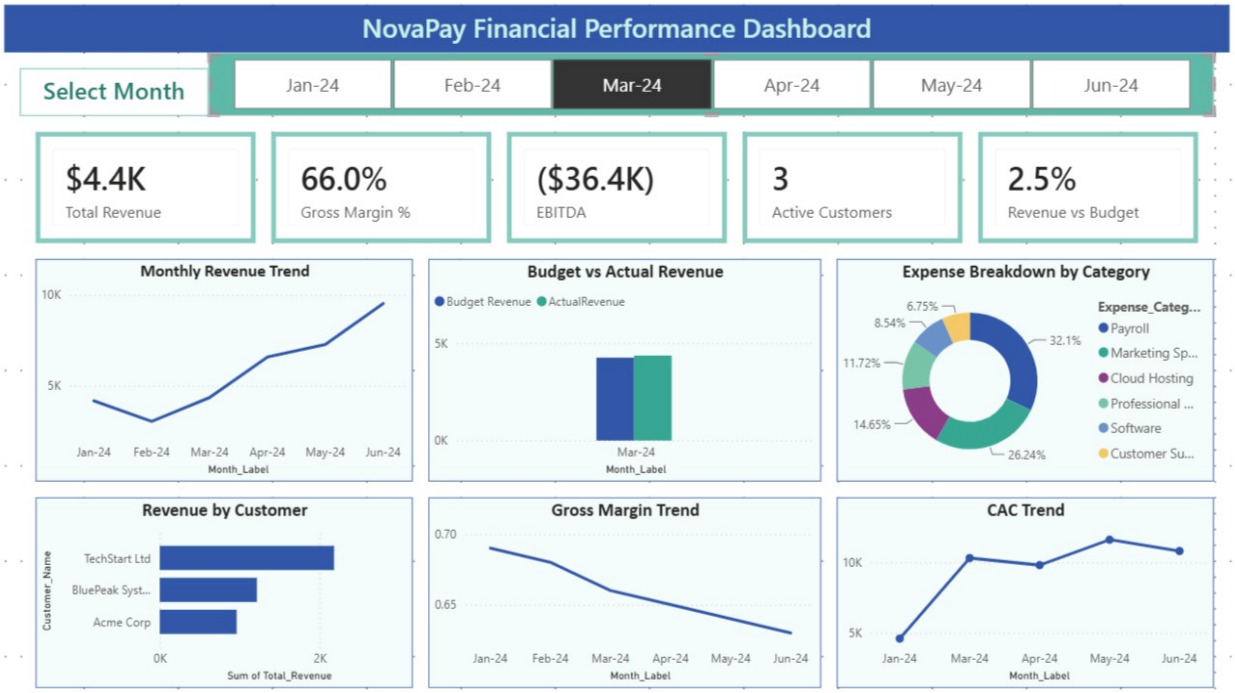

This project combines financial modeling, SQL analysis, Python scenario analysis, and Power BI dashboarding into one complete analytics project.

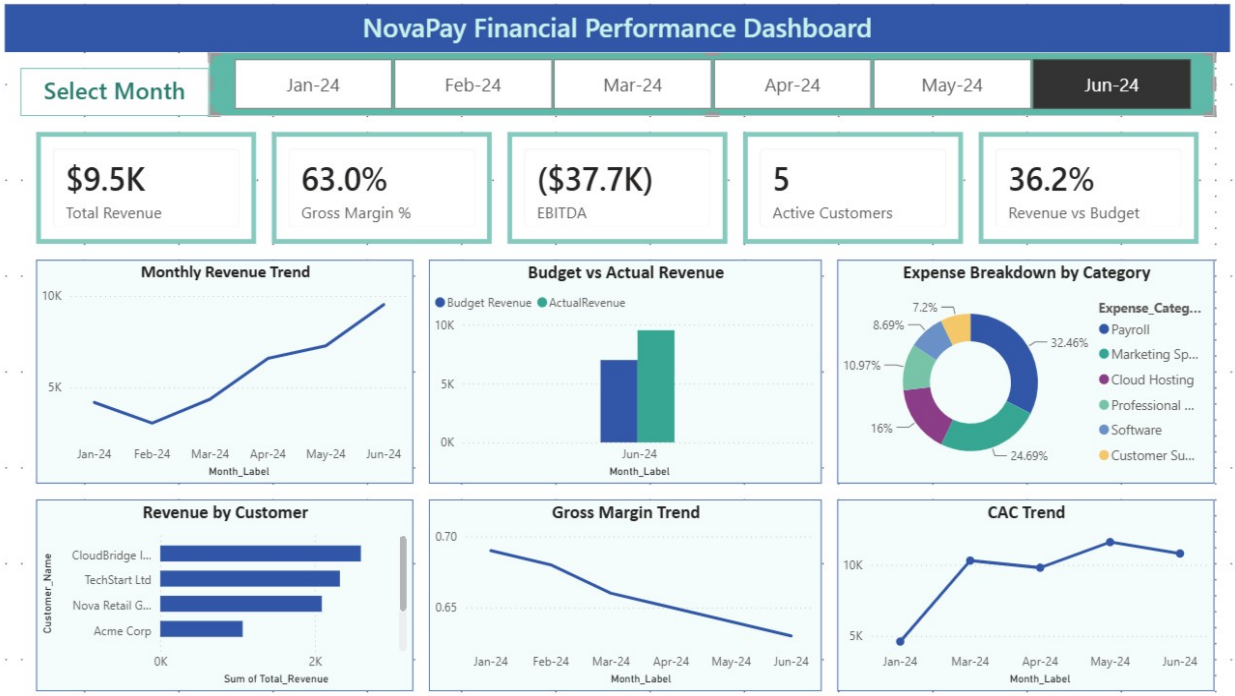

The final dashboard helps users understand business performance through revenue trends, budget comparisons, expense analysis, customer revenue contribution, profitability metrics, and acquisition cost trends.

It shows how financial data can be converted into useful business insights through a structured analytics workflow.
